Question: What are the main causes of ocean currents?

Answer: Ocean currents are primarily driven by a combination of factors:

Wind Patterns: Surface currents are mainly caused by prevailing winds such as the trade winds and westerlies. These winds exert friction on the ocean surface, initiating movement.

Coriolis Effect: The Earth's rotation deflects moving water to the right in the Northern Hemisphere and to the left in the Southern Hemisphere, influencing current paths.

Density Differences: Variations in temperature (thermohaline effect) and salinity create density gradients that drive deep ocean currents, forming the global thermohaline circulation.

Seafloor Topography: Underwater features like ridges and basins influence current pathways by channeling or blocking flow.

Gravity: Tides generated by the moon and sun influence surface water movement.

Understanding these factors reveals the complex, interconnected system that maintains Earth's climate regulation and nutrient distribution.

Question: How does coral bleaching occur?

Answer: Coral bleaching is a stress response where corals expel their symbiotic algae, zooxanthellae, leading to a loss of color and vital energy sources. The process occurs due to:

Elevated Sea Temperatures: Temperature increases beyond the normal range cause cellular stress.

Excess Solar Radiation: High sunlight levels can exacerbate thermal stress.

Ocean Acidification: Increased CO₂ lowers seawater pH, impairing calcification and coral health.

Pollution and Sedimentation: Contaminants and sediment smother corals and hinder their ability to cope with stress.

Disease and Overexposure to UV Rays: Additional stressors weaken coral resilience.

Without their symbiotic algae, corals become more susceptible to disease and mortality, disrupting reef ecosystems.
